About the Medicine

What is Viagra 100mg?

Viagra 100mg is a prescription medication primarily used to help treat erectile dysfunction in adult men. Erectile dysfunction occurs when a person has difficulty achieving or maintaining an erection suitable for sexual activity.

Viagra works by increasing blood flow to specific areas of the body during sexual stimulation. The medication does not automatically cause an erection but helps improve the body's natural response when sexual arousal occurs.

Viagra became one of the first widely known oral medications approved for erectile dysfunction treatment and remains commonly prescribed worldwide.

Drug Class

Phosphodiesterase Type 5 (PDE5) Inhibitor

Common Uses

Some pharmacies may also provide generic sildenafil products in additional strengths depending on local regulations and manufacturer availability.

How Viagra 100mg Works

Viagra belongs to a class of medications known as PDE5 inhibitors. These medicines work by relaxing blood vessels and improving blood circulation in certain areas of the body.

When a man becomes sexually stimulated, nitric oxide is naturally released in the body. This process helps relax muscles and increase blood flow to the penis. Viagra supports this natural response by preventing the breakdown of a chemical called cyclic guanosine monophosphate (cGMP), which helps maintain improved blood flow.

The result may help individuals achieve and maintain an erection during sexual activity.

It is important to understand that Viagra only works with sexual stimulation. It is not intended to increase sexual desire or function as an aphrodisiac.
